Purpose: The primary aim of this study was to investigate, using an experimental rat model of osteoarthritis(OA), the effect of a selective p38 mitogen activated protein kinase inhibitor,SB203580, on the development of structural changes.Additional aims were to assess the effects of the inhibitor on levels of matrixmetalloproteinase 3 (MMP-3) and MMP-13(collagenase 3) in OA cartilage and to explore the relation between the MMP-3,13 expression and the severity of OA.
Methods: OA was induced in 40 SD rats by anterior cruciate ligament transection (ACLT).After surgical, rats with OA were randomly divided into A_D groups: Rats of group A received 0.1 ml intra-articular injection of SB203580 at high concentration of 100um/L. Each treatment started immediately after surgery, once a week;those in group B were treated under the same condition using SB203580 with low concentration of 10um/L and those in group C received 0.1ml of intra-articular 0.9% Sodium Chloride injection,animals of group D were not injected as controls after ACLT. The animals were killed 8 weeks after surgery. Macroscopicand histologic studies were performed on the cartilage. The levels of MMP-3,13 in OA cartilage chondrocytes were evaluated by immunohistochemistry and western-blotting.
Results: All ACLT knees demonstrated osteoarthritic changes. Cartilage degradation in the control group was significantly more severe than that in the experimental group both on the macroscopic grading scale and on Mankin's grading scale($P < 0.05$). Immunohistochemical study showed that in the experimental group MMP-3,13 was predominantly expressed in the superficial and upper intermediate layers of cartilage, and the amount of MMP-3,13 in the experimental group was also lower than that in control group($P < 0.05$). In western-blotting the amount of MMP-3,13 was reduced by the treatment of the inhibitor. The protein levels of MMP-3 and MMP-13 in cartilage of inhibitor injection groups were significantly lower than those of Sodium Chloride group and untreated group. There was no significant difference in MMP-3 and MMP-13 expression between the different concentration inhibitor injection groups. No significant difference in MMP-3 and MMP-13 expression in cartilage was found between Sodium Chloride group and control group.
Conclusions: This study demonstrates that, in vivo,SB203580, a selective inhibitor of p38MAPK, can partially decrease the development of some of the structural changes in the early phases of experimental OA and significantly reduces the severity of cartilage degradation. This effect was associated with a reduction in the level of MMP-3,13 in OA cartilage, which probably explains the action of the drug and thus may be a potential drug for the treatment of OA.

INVOLVEMENT OF TYROSINE PHOSPHORYLATION IN THE ACTIVATION PROCESS OF THE VOLUME SENSITIVE Cl^- CHANNEL IN RABBIT ARTICULAR CHONDROCYTES

Purpose: Mechanical loading of articular cartilage influences the metabolism of extracellular proteoglycan and collagen matrix and thereby alters the osmotic environment surrounding chondrocytes. Previous studies have identified the presence of the stretch-activated cation channels, mechanosensitive K^+ channels and volume-sensitive Cl^- channels ($I_{Cl,vol}$) in chondrocytes, suggesting that these mechanosensitive ion channels contribute to cell volume regulation. Pathological swelling of chondrocytes observed in osteoaethritic (OA) cartilage may be ascribed at least partly to the impairment of channel function involved in the volume-regulatory process.The present study was designed to elucidate the mechanisms underlying activation of $I_{Cl,vol}$ in rabbit articular chondrocytes using whole-cell patch-clamp method.
Methods: Rabbit cartilages were collected from bilateral knee, hip and glenohumeral joints of male animals weighing 2.0 to 3.0 kg. The cartilage was dissected into slices and cultured in DMEM for 1-3 days, and chondrocytes were isolated by enzymatic digestion on the day of experiments. Whole-cell membrane current was recorded during exposure to isosmotic (300 mOsm), hyposmotic (210 mOsm) and hyperosmotic (350 mOsm) external solutions under conditions where Na^+, K^+ and Ca^{2+} currents were minimized. In some experiments, the stretch-activated cation current was also blocked by external application of 30 μM Gd^{3+}.
Results: Exposure of chondrocytes to the hyposmotic solution resulted in a cell swelling (27.0±2.7% increase in diameter, n = 28), which was accompanied by the activation of $I_{Cl,vol}$. External application of tyrosine kinase inhibitor genistein (30 μM) partially (42.0±14.3%, n = 7) and reversibly blocked $I_{Cl,vol}$ but its inactive analogue daidzein (30 μM) had no effect. On the other hand, intracellular application of tyrosine phosphatase inhibitor orthovanadate (250 and 500 μM) via a recording pipette gradually activated an outwardly rectifying current with a reversal potential (-20.3±0.58 mV, n = 13) close to the predicted Cl^- equilibrium potential (E_{Cl}- = -18.3 mV) even under isosmotic condition. This orthovanadate-evoked current was almost completely abolished by the stilbene-derivative Cl^- channel blocker DIDS (dihydro-4,4' diisothiocyanostilbene-2,2'-disulphonic acid, 500 μM) and was also largely reduced by cell shrinkage caused by exposure to hyperosmotic solution. These observations indicate that orthovanadate activates a Cl^- conductance which is sensitive to cell volume change. Pretreatment of chondrocytes with genistein significantly prevented the activation of Cl^- current by othovanadate, suggesting that the basal activity of tyrosine kinase is required for the orthovanadate-evoked activation of Cl^- current.
